Of Americans prefer getting their news from websites

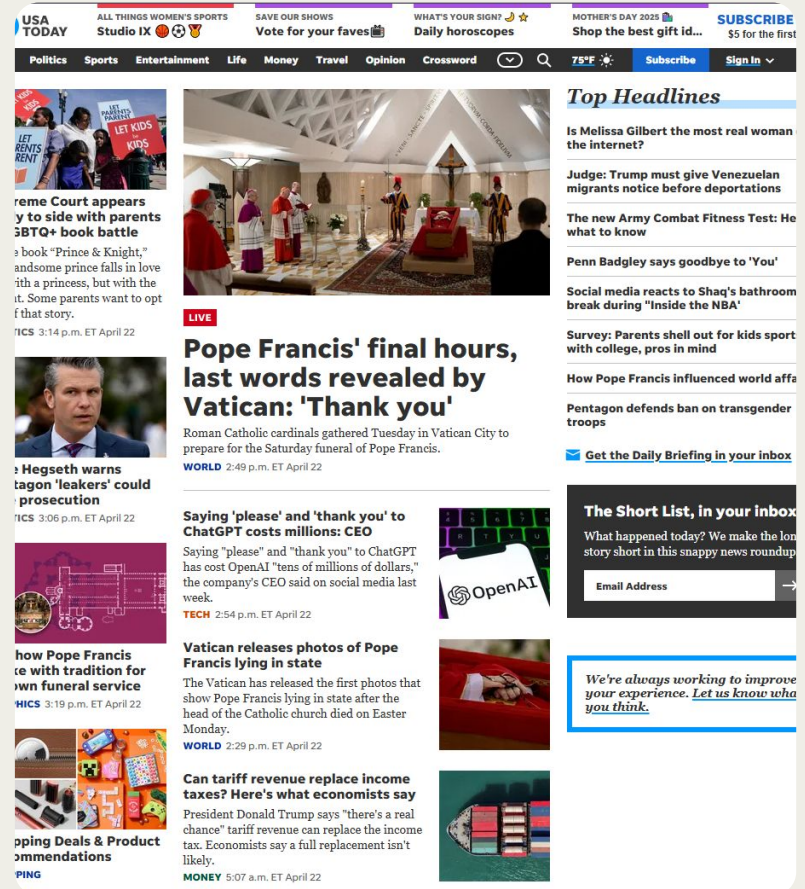

1.48 minutes

Average time spent per visit on news websites

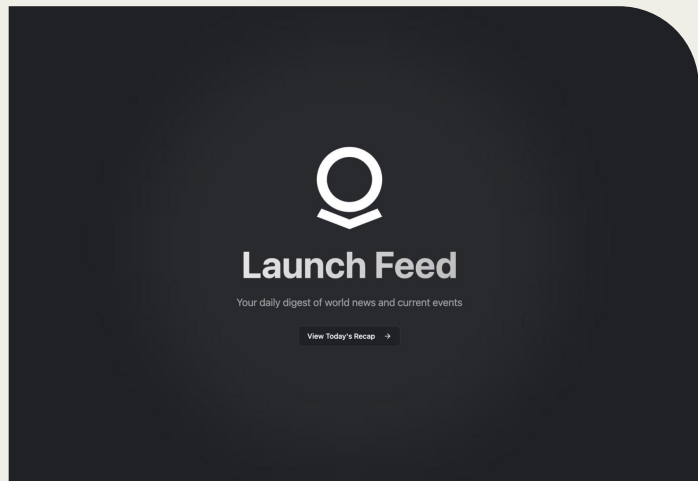

(Pew Research Center, 2023)

Problem Statement

- Modern news sites are overwhelming
- News is fragmented, algorithmically biased, and lacking structured context
- Users waste time sifting noise for signal
- There's no clear way to answer: "What happened today?"

Platform Overview

- Launch Feed is a news aggregator that delivers structured recaps of any day's headlines from the past 20 years. Select a date, and Launch Feed pulls in articles, clusters them by topic, and generates summaries using AIP logic.
- It includes advanced search with filters for date, source, and category, aggregating results from multiple feeds. The platform is built on the Foundry platform, leveraging its data processing and LLM capabilities to provide clear, contextual news analysis.
- Launch Feed strips out the noise presenting just the facts, in one central location.

System Architecture

Data Ingestion

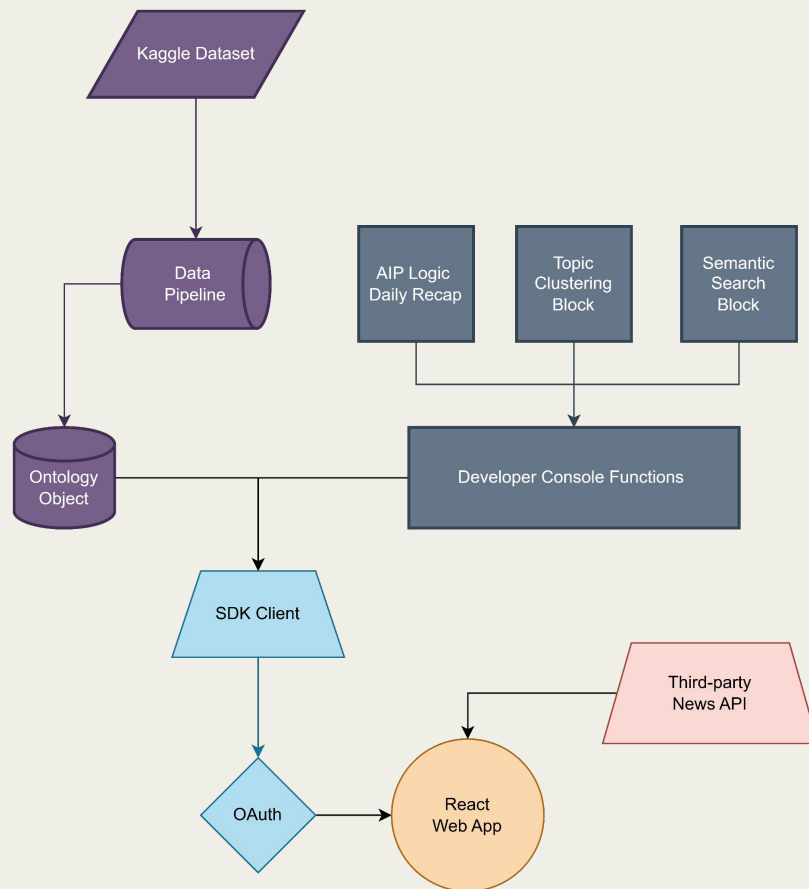

- Pulls articles (2000–present) from a Kaggle dataset
- Live news as it breaks from third-party APIs

Logic Functions

- AIP Logic generates daily recap + sentiment score
- Topic Clustering groups related articles by topic
- Semantic Search enables headline / source querying

OSDK Integration

- Create ontology objects + console functions
- Combine all backend logic into an SDK client
- React frontend connects to Foundry through this client, handling all data interactions

Difficulties / Future Outlooks

1.

Working with large dataset 2M+ rows

Foundry's manual uploader has a 1 GB limit, which blocked direct upload of my full dataset. I followed a solution from the Palantir Developer Community that uses a parquet-based ingest pipeline to stream large files into the platform in chunks.

2.

Integrating OSDK with custom react frontend

Getting started with the OSDK was challenging as I had trouble linking it to my React frontend, and handling OAuth added more complexity. But building a clean, responsive UI was central to the product. That integration now powers the core user experience.

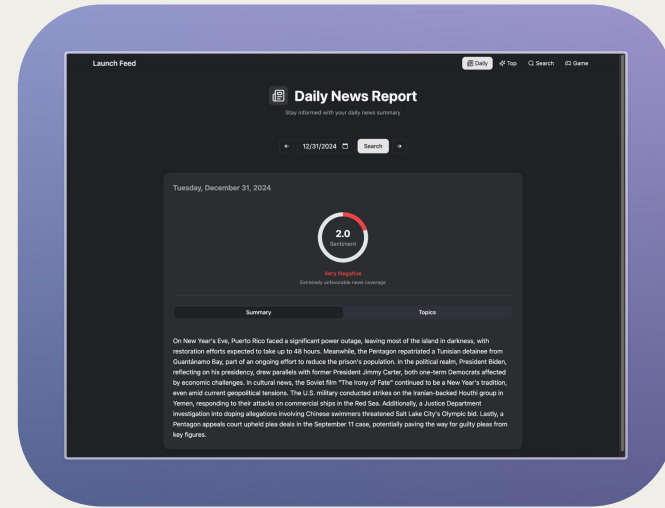

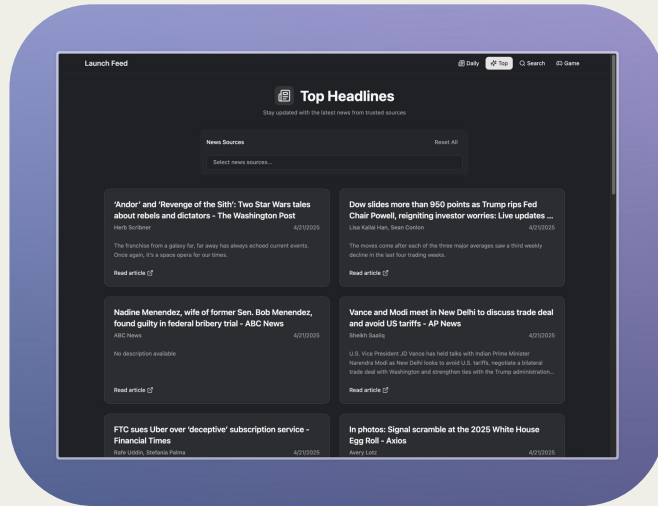

3.

Improving semantic search quality

Early search results were inconsistent due to token mismatches and vague user queries. Future work includes tuning embedding context, better sentiment analysis, and refining topic clustering for smarter results.

Designed for how people read

A stripped-down interface that removes distractions.

Smart grouping, smarter reading

For users to understand the bigger picture—faster.

Thanks!
